**PREFILED RESPONSE TESTIMONY  
OF LUKE P. HANSEN  
ON BEHALF OF NORTHWESTERN ENERGY**

**TABLE OF CONTENTS**

<b><u>Description</u></b>	<b><u>Starting Page No.</u></b>
Witness Information	2
Purpose of Testimony	2
Power Sim Model	3
NorthWestern's Current Avoided Cost	5
<b><u>Exhibit</u></b>	
Avoided Cost – Juhl Wind	Exhibit __ (LPH-1)

LPH-1

1 **Witness Information**

2 **Q. Please state your name and business address.**

3 **A.** My name is Luke P. Hansen, and my business address is 11 East Park,  
4 Butte, Montana 59701.

5  
6 **Q. By whom are you employed and in what capacity?**

7 **A.** I am employed by NorthWestern Energy ("NorthWestern") as an analyst in  
8 Energy Supply.

9  
10 **Q. Please summarize your educational and employment experiences.**

11 **A.** I graduated from Montana Tech in 2003 with a Bachelor of Science  
12 degree in Business and Information Technology. Prior to joining  
13 NorthWestern, I was a supervisor of Gas Supply at Cascade Natural Gas.  
14 I joined NorthWestern in November 2013 as an Energy Supply Analyst. In  
15 this position, I assist in the development of the Electric Supply Resource  
16 Procurement Plans for NorthWestern's service territories and the Montana  
17 Renewable Portfolio Standard Compliance filing. I am the NorthWestern  
18 employee who is trained to use the PowerSimm™ ("PowerSimm")  
19 software with which NorthWestern models its electricity supply.

20  
21 **Purpose of Testimony**

22 **Q. What is the purpose of your testimony in this docket?**

1 **A.** I describe the PowerSimm modeling software, explain why NorthWestern  
2 chose PowerSimm™ to model its electric supply portfolios, and rebut Juhl  
3 Energy, Inc. (“Juhl’s”) witness, Roger Schiffman’s assertions about the  
4 transparency of the PowerSimm model. I identify and support the avoided  
5 cost energy rate that NorthWestern calculated for the Juhl’s proposed  
6 Qualifying Facility (“QF”) projects (“Projects”) using the PowerSimm model  
7 and discuss other issues that affect and influence the avoided cost rate for  
8 energy sold by QFs.

9

10 **PowerSimm Model**

11 **Q. What is PowerSimm?**

12 **A.** PowerSimm is software that NorthWestern uses to model costs and risks  
13 to its portfolio. PowerSimm uses a stochastic modeling approach that  
14 considers uncertainty to quantify the effects of variation in load, renewable  
15 generation, and market prices on a simulated portfolio. The modeling  
16 simulations are performed on an hourly time series in order capture the  
17 changes that renewable generation and market prices have in relation to  
18 NorthWestern's portfolio.

19

20 Because weather and load, weather and renewable generator output, and  
21 weather, load, renewable generation and commodity prices have historical  
22 relationships and are dependent on each other, PowerSimm maintains the  
23 structural relationships that have been observed in the historic data

1 throughout the simulation process. Maintaining those structural  
2 relationships allows PowerSimm to probabilistically quantify the variability  
3 in simulated future conditions. PowerSimm models the impact of load  
4 variability, renewable generation, and market prices on the distribution of  
5 possible portfolio-level costs.

6  
7 PowerSimm models load, renewable generation units, thermal generation  
8 units, and commodity prices. The simulation engine starts with weather,  
9 which drives load and renewable generation. The load and renewable  
10 generation determine the spot prices, which in turn drive the economic  
11 dispatch of thermal generation units. The difference between total thermal  
12 and renewable generation load determines a net position of the portfolio.

13  
14 NorthWestern employs PowerSimm to model all new electric energy  
15 resources, including company-owned, power purchase agreements, and  
16 QFs, for inclusion in NorthWestern's portfolios. PowerSimm performs unit  
17 level simulation that is aggregated to a portfolio level. The unit level  
18 simulation allows NorthWestern to model the effect that alternative  
19 resources have on its energy supply portfolio and allows for detailed  
20 analysis of potential additional resources to the portfolio.

21  
22 **Q. Why does NorthWestern use PowerSimm instead of more common**  
23 **generation and transmission modeling software?**

1 **A.** Previously, NorthWestern used GenTrader® for resource planning and  
2 evaluation. In its comments on NorthWestern’s electric resource  
3 procurement plans for 2007, 2009, and 2011, the Montana Public Service  
4 Commission (“MPSC”) questioned the use of GenTrader®. When it  
5 began preparing its 2013 Montana electricity resource procurement,  
6 NorthWestern contacted software vendors and evaluated the capabilities  
7 of many alternatives. NorthWestern chose PowerSimm™ (“PowerSimm”)  
8 from Ascend Analytics (“Ascend”) because of the capability of the model,  
9 the consulting ability of Ascend Analytics, the validation steps that Ascend  
10 performs, and the vendor support Ascend offers.

11

12 **Q.** What specific characteristics of PowerSimm led to NorthWestern’s  
13 choice?

14 **A.** Several characteristics of PowerSimm stood out. First, it incorporated  
15 stochastic uncertainty better than the alternatives. It uses and provides an  
16 expanded set of variables. NorthWestern felt it provided the most robust  
17 solution for modeling load, supply portfolio resources, commodity prices,  
18 and portfolio costs while maintaining fundamental relationships between  
19 these variables and weather.

20

21 **NorthWestern’s Current Avoided Cost**

22 **Q.** Describe the inputs NorthWestern used to model Juhl Wind’s  
23 proposed projects.

1 **A.** The inputs entered into PowerSimm are historic weather, historic load,  
2 historic commodity prices for energy, coal, natural gas, historic hourly and  
3 forecasted monthly peak and total renewable generation, thermal  
4 generation attributes, projected load growth, and projected commodity  
5 prices for natural gas, electricity, and coal. These inputs are described in  
6 more detail below.

7  
8 The inputs for NorthWestern's load are hourly historic load and forecasted  
9 monthly peak and demand values for its South Dakota service territory.

10 The historic hourly load determines the load shape to match forecasted  
11 monthly demand and peak demand values throughout the simulation  
12 process. NorthWestern forecasts its monthly load by escalating the  
13 historical demand profile by projected future growth.

14  
15 Renewable generation units include the wind resources that are either  
16 contracted for or owned by NorthWestern. Each renewable asset is  
17 defined by its historical hourly production profile and monthly peak and  
18 total generation projection. The hourly generation provides the daily  
19 production profile throughout the simulation. The monthly forecasts are  
20 the average of the historical monthly generation and the peak production  
21 is defined by the monthly historical peak generation.

22

1  
2  
3  
4  
5  
6  
7  
8  
9  
10  
11

The thermal generation units included in this calculation are the thermal generation resources that are in NorthWestern's energy supply portfolio. The thermal generation units' resource definition consists of startup costs, ramp rates, outage history, heat rates, emissions, and fuel delivery costs. The unique operating characteristics and costs of each thermal resource are reflected through the parameters that are defined in PowerSimm allowing the model to accurately dispatch or utilize such resource.

Table 1 below lists all of the generation assets entered into the model for NorthWestern's portfolio.

1  
2

**Table 1**

<b>South Dakota Supply Portfolio</b>					
		<b>Max. Delivery (MWh)</b>	<b>Avg. Delivery (MWh)</b>	<b>Min. Delivery (MWh)</b>	
<b>Wind</b>	Titan (non-dispatchable)	25	11	0	PPA
	Oak Tree (non-dispatchable)	20	8	0	PPA
	Beethoven (non-dispatchable)	76	33	0	Owned
<b>Coal</b>	Neal 4 (Must Run)	17	17	17	Contracted Min
	Coyote (Must Run)	20	20	20	Contracted Min
	Big Stone (Must Run)	44	44	44	Contracted Min
	<b>MUST RUN</b>	<b>202</b>	<b>133</b>	<b>81</b>	
<b>Coal</b>	Neal 4 (Dispatchable)	41	33	0	Avg Heat Curve
	Coyote (Dispatchable)	23	15	0	Avg Heat Curve
	Big Stone (Dispatchable)	67	11	0	Avg Heat Curve
<b>Peaking</b>	Aberdeen #2	58	1	0	Full Load
	Huron #2	40	0	0	Full Load
	Huron #1	10	0	0	Full Load
	Aberdeen #1	20	0	0	Full Load
	<b>DISPATCHABLE</b>	<b>259</b>	<b>60</b>	<b>0</b>	
	<b>Total Supply</b>	<b>461</b>	<b>193</b>	<b>81</b>	

3  
4

5 Finally, commodity prices for natural gas, electricity, and coal are  
 6 developed and entered into PowerSimm. The market price forecasts for  
 7 natural gas and electricity are a combination of current forward market  
 8 prices and the application of long-term price escalation factors.  
 9 NorthWestern projected natural gas prices by starting with Intercontinental  
 10 Exchange ("ICE") forward market quotes through October 2017 and  
 11 escalated them forward at the annual escalation rate from the 2016

1 Energy Information Administration (“EIA”) Annual Energy Outlook (“AEO”)  
2 for natural gas. NorthWestern projected market prices for electricity by  
3 using ICE quoted prices December 2018 and then escalated those values  
4 at the 2016 EIA AEO escalation rate for natural gas. NorthWestern uses  
5 the natural gas escalation rates to forecast its electric price to maintain  
6 consistency in escalation factors and because natural gas generation is  
7 often the marginal unit in the market. NorthWestern used natural gas and  
8 electricity price quotes from the October 4, 2016 ICE forward market  
9 prices in this docket.

10  
11 NorthWestern used its internal coal price forecasts for Big Stone, Coyote,  
12 and Neal. The internal coal forecasts for Coyote, Big Stone and Neal  
13 extend to 2021, 2024, and 2025 respectively. For periods after the end of  
14 the internal forecasts, NorthWestern escalated the projected prices using  
15 the 20-year average inflation escalator for Gross Domestic Product as  
16 provided by the U.S. Bureau of Economic Analysis.

17  
18 **Q. What happens after the inputs are uploaded in the PowerSimm™**  
19 **modeling?**

20 **A. PowerSimm calculates the hourly dispatch of NorthWestern’s supply**  
21 **portfolio. The model performs 100 simulations for every hour of the 20-**  
22 **year period. First, PowerSimm simulates weather. Then the model uses**  
23 **the simulated weather to simulate load and renewable generation output.**

1 The historical relationships between weather and load and weather and  
2 renewable generation are maintained throughout the simulation process.  
3 Using weather, load, and renewable generation output, PowerSimm  
4 simulates market prices. Using market prices, the model economically  
5 dispatches the thermal generation units. The model calculates the net  
6 position—i.e. whether the portfolio needs energy or has an excess of  
7 energy—using the total output of the thermal and renewable generation  
8 units and load. The same process is repeated with Juhl's projects added  
9 to NorthWestern's supply portfolio.

10

11 **Q. How do the simulation results lead to the calculation of the avoided**  
12 **energy cost?**

13 **A.** NorthWestern compares the net position of the existing supply portfolio  
14 without the Projects to the net position of the supply portfolio with them to  
15 determine their effect on NorthWestern's supply portfolio. For example, if  
16 the Projects deliver energy to NorthWestern when NorthWestern's supply  
17 portfolio is short (i.e. generation is less than load), the avoided energy cost  
18 is the market purchase price of electricity that NorthWestern would  
19 otherwise have purchased. Alternatively, if the Projects deliver energy to  
20 NorthWestern when NorthWestern's supply portfolio is long (i.e.  
21 generation is greater than load) and the market price is higher than the  
22 variable cost of the highest economically dispatchable resource used to  
23 serve load, the avoided energy cost is the variable cost of the

1 dispatchable resource that was serving load. Finally, if the Projects  
2 deliver energy to NorthWestern when NorthWestern's supply portfolio is  
3 long and the market price is lower than the variable cost of any  
4 dispatchable resource, the avoided energy cost is zero. The LaFave  
5 Response Testimony supports why it is appropriate to attribute no avoided  
6 cost value to Juhl Wind production under this scenario.

7  
8 Table 2 below summarizes the different supply portfolio conditions under  
9 which Juhl Wind could deliver energy to NorthWestern and the avoided  
10 energy cost rate that NorthWestern would pay it under each scenario.

11

**Table 2**

<b>Condition</b>	<b>Condition Definition</b>	<b>Avoided Cost energy rate paid for Crazy Mountain</b>
<b>Situation 1</b>	Generation < load.	Market purchase price
<b>Situation 2</b>	Generation > load and market price > avoidable resource with the highest variable cost.	Variable costs of the dispatchable resource with the highest variable costs
<b>Situation 3</b>	Generation > load and market price < variable cost of the avoidable resources.	Zero

1 To summarize, the Projects' monthly production that offsets purchases is  
 2 multiplied by the corresponding market purchase price to determine the  
 3 amount paid to Juhl during this condition. The Projects' production that  
 4 occurs when NorthWestern's net position is long i.e., has excess  
 5 generation, is totaled for each month and is multiplied by the variable cost  
 6 of the highest cost dispatchable resource during times when the market  
 7 sales price is higher than the variable cost of the highest cost dispatchable  
 8 resource to determine the amount paid to Juhl. The Projects' monthly  
 9 production delivered during times that the portfolio is long and the market

1 sales price is lower than the variable cost of any dispatchable resource is  
2 valued at zero because it does not allow NorthWestern to avoid any cost.

3  
4 Next, NorthWestern totals monthly avoided cost energy values for the  
5 Projects for each year and divides the total by their yearly annual  
6 production to calculate an annual avoided cost energy rate for the  
7 Projects. NorthWestern then calculates the net present value of this  
8 stream of annual rates and levelizes it over 20 years to determine the  
9 Projects' avoided energy cost rate for this filing.

10

11 **Q. What is the cost for energy that NorthWestern can avoid by**  
12 **purchasing the output of the Juhl Wind projects?**

13 **A.** The cost for energy that NorthWestern can avoid by purchasing the output  
14 of the Projects is \$28.49 per megawatt-hour ("MWh") for the contract term  
15 of 2017-2036. Recent information from SPP has made a 2017 commercial  
16 operation date unlikely and due to this, NorthWestern is also providing a  
17 levelized rate for energy from 2018-2037. The levelized energy rate for the  
18 contract term of 2018-2037 is \$29.63 per MWh. Both rates are 20-year  
19 levelized rates. Exhibit\_\_(LPH-1) details this calculation of the avoided  
20 cost using the PowerSimm modeling for both contract terms of 2017-2036  
21 and 2018-2037.

1 **Q. Why did NorthWestern use the October 4, 2016 ICE forward prices as**  
2 **the basis for the natural gas and electric price forecasts used in this**  
3 **docket?**

4 **A.** As described and supported in the Prefiled Response Testimony of Bleau  
5 J. LaFave ("LaFave Response Testimony"), Juhl has not established a  
6 legally enforceable obligation. Given this fact, in order to obtain the most  
7 current information for purposes of calculating an avoided cost rate,  
8 NorthWestern selected the date closest to when NorthWestern's testimony  
9 was due that allowed adequate time for NorthWestern to run the model  
10 and prepare the corresponding testimony.

11  
12 **Q. Why are the forecasts NorthWestern proposed for natural gas and**  
13 **electricity prices appropriate to use in this case?**

14 **A.** The natural gas and electric forecasts used in this docket are a  
15 combination of near term market transactions and long-term escalation  
16 rates. NorthWestern bases the forecasts on real market prices and the  
17 EIA forecasted escalation rate. These forecasts represents the most  
18 current reliable, fundamental information of market forecasts applicable to  
19 NorthWestern.

20  
21 Using prices from the closest liquid electric trading point, SPP North,  
22 provides short-term future prices based on current market expectations.  
23 Applying the EIA escalation rate to the remaining years results in a

1 market-based forecast using publicly available information. This  
2 calculation is valid, easily replicated, and transparent. Additionally,  
3 NorthWestern uses this forecasting methodology for the evaluation of  
4 NorthWestern's recent planning and evaluation decisions.

5  
6 **Q. Juhl witness Roger Schiffman contends that NorthWestern has not  
7 been transparent with its use of PowerSimm. Do you agree?**

8 **A.** No, I do not agree. Juhl filed Mr. Schiffman's testimony prior to asking its  
9 first set of Data Requests on August 17, 2016. NorthWestern provided all  
10 available data and explained its use of PowerSimm in its responses to that  
11 discovery. Just as Juhl could not provide the ABB/Ventyx data to  
12 NorthWestern, NorthWestern cannot provide Ascend's data to Juhl. If  
13 Juhl wants access to Ascend's intellectual property, that can be arranged  
14 for a fee paid to Ascend. NorthWestern and Ascend are willing to support  
15 independent parties in their review and access to PowerSimm. Ascend  
16 hosts PowerSimm in a private cloud. The most cost-effective approach to  
17 reviewing PowerSimm inputs will be to have Ascend staff serve as user  
18 experts on behalf of the independent party. With Ascend serving as the  
19 operational tour guide, independent parties will be able to readily review  
20 portfolio configuration and modeling assumptions.

21  
22 Ascend will work cooperatively with the independent parties if they have a  
23 desire to review input assumptions. The reviewer will have the ability to

1 view relevant input configurations for the avoided cost study through the  
2 PowerSimm user interface used to generate the results; including market  
3 forward curves, generation asset characteristics, wind generation history,  
4 weather, and other applicable inputs.

5  
6 The fee for the guided tour of PowerSimm will be an estimated \$3,000.  
7 Creating a software tour requires creation of an independent reviewing  
8 environment that costs \$2,000 in labor effort to establish. There will be  
9 approximately another \$1,000 for a two hour review session run by two  
10 Ascend staff members billed at Ascend standard commercial consulting  
11 rates (approximately \$250/hr \* 2hr \*2 staff) for a total cost of \$3,000 for the  
12 preliminary review. The review sessions will be conducted at either  
13 Ascend's offices in Bozeman or Boulder or remotely at the options of the  
14 reviewer.

15  
16 If there is a request to run analyses to look at particular output results,  
17 computing resources are available at \$5,000 per month for three computer  
18 workstations and \$500 per month per terabyte of database storage.

19 Standard commercial consulting rates also apply for Ascend staff  
20 performing or assisting with running these analyses.

21  
22 **Q. Does this conclude your response testimony?**

23 **A. Yes, it does.**

## CERTIFICATE OF SERVICE

I, the undersigned, hereby certify that on the 17th day of October, 2016, true and correct copies of the foregoing, PREFILED RESPONSE TESTIMONY OF LUKE P. HANSEN ON BEHALF OF NORTHWESTERN ENERGY and exhibit in Docket No. EL16-021, were served on the following via electronic mail:
